The coefficients get inverted (one over their previous value).

The coefficients reverse their signs.

The coefficients change in a non-linear fashion.

4. Consider the insect spray data **InsectSprays**. Fit a Poisson model using spray as a factor level. Report the estimated relative rate comapring spray A (numerator) to spray B (denominator).

1 / 1 points

0.9457

-0.056

Correct

1 fit <- glm(count ~ relevel(spray, "B"), data = InsectSprays, family = poisson
)
2 exp(coef(fit))[2]

1 ## relevel(spray, "B")A
2 ## 0.9457</pre>

0.321

0.136

Consider a Poisson glm with an offset, t. So, for example, a model of the form glm(count x + offset(t), family = poisson) where x is a factor variable comparing a treatment (1) to a control (0) and t is the natural log of a monitoring time. What is impact of the coefficient for x if we fit the model glm(count x + offset(t2), family = poisson) where 2 < -log(10) + t? In other words, what happens to the coefficients if we change the units of the offset variable. (Note, adding log(10) on the log scale is multiplying by 10 on the original scale.)

The coefficient estimate is unchanged

The coefficient is subtracted by log(10).

The coefficient estimate is divided by 10.

This should not be selected

The coefficient estimate is multiplied by 10.

Consider the data

1 / 1 points

Using a knot point at 0, fit a linear model that looks like a hockey stick with two lines meeting at x=0. Include an intercept term, x and the knot point term. What is the estimated slope of the line after 0?

2 y <- d(5.12, 3.93, 2.67, 1.87, 0.52, 0.08, 0.93, 2.05, 2.54, 3.87, 4.97)

-0.183

1 x <- -5:5

-1.024 1.013

1.013

Correct

1 z <- (x > 0) * x
2 fit <- lm(y ~ x + z)
3 sum(coef(fit)[2:3])

1 ## [1] 1.013</pre>

2.037
